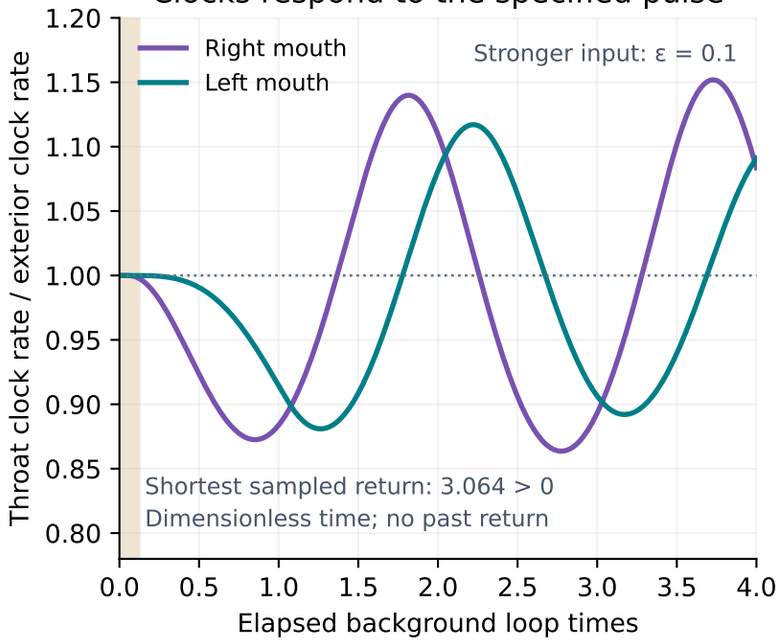
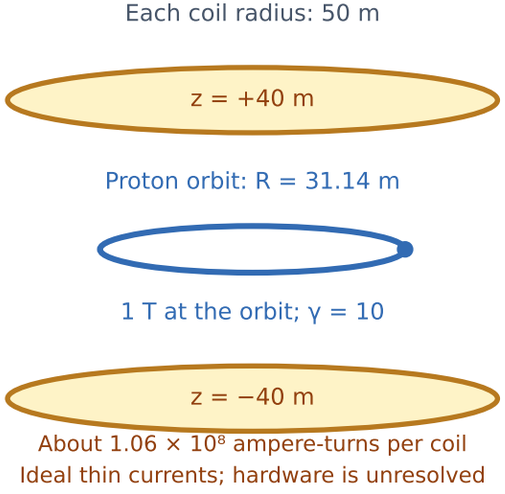
The throat response now balances; one coil field confines the model proton

Two verified model advances — an assumed throat with dynamical clocks, and ideal filament-coil storage

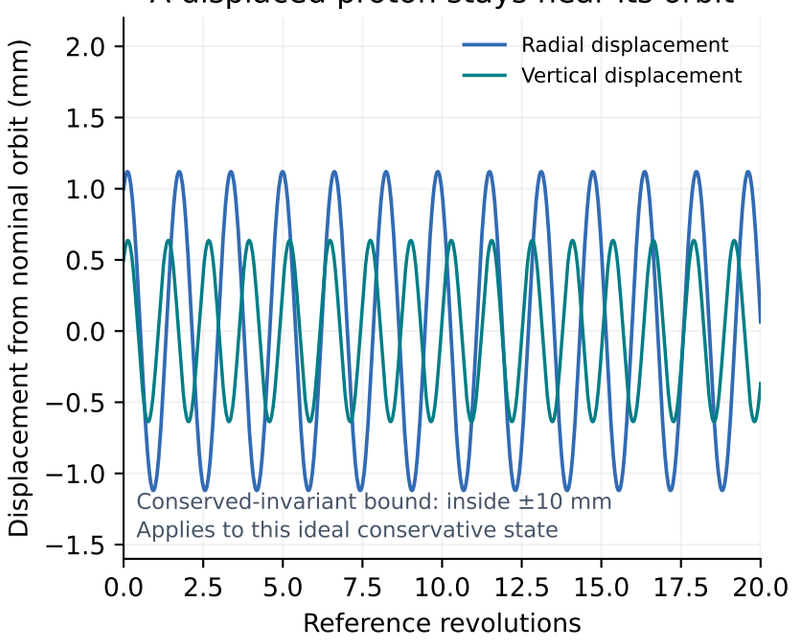
Clocks respond to the specified pulse



Two source coils (schematic)



A displaced proton stays near its orbit



Past: gravity matching, returned quantum stress and the energy ledger agree. All tested pulses still give forward returns.

Future: one field from explicit coil locations supports the orbit and its confinement bound. Leaving it requires a separately modeled control.

Next: stress-test the coupled throat within its validity limits; add extraction control to this same coil field. No physical throat has been created.

13 → 12 Sep 2027: unproved. 13 → 14 Sep: supported time dilation; one-day storage and retrieval are not demonstrated here.
