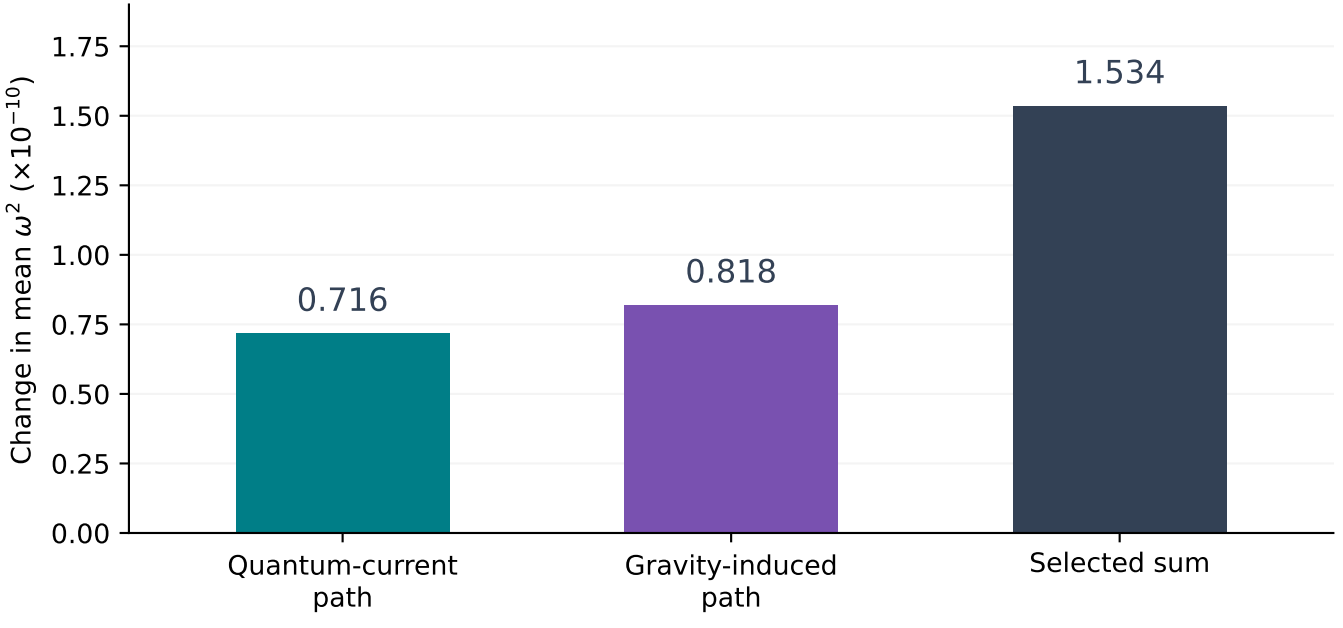
Two path corrections are comparable; clock matching still matters

Conditional static model | Same radial mean response applied to all three bars | $\alpha = 10^{-9}$



Separate clock matching test

Impose test offset $+\eta = m/d$

Additional mean change

0.896×10^{-10}

Physical offset remains undetermined.
This is not an uncertainty bound
and is not included in the bars.

Shapiro delay is already in the baseline; the new gravity term adds path bending only.

Physical mouth matching and nonspherical response remain unresolved; these bars are not a stability test.

A positive static lapse and shared time exclude backward travel within this assumed model.

No constructed stable medium or 13 → 12 Sep 2027 passage demonstrated.
