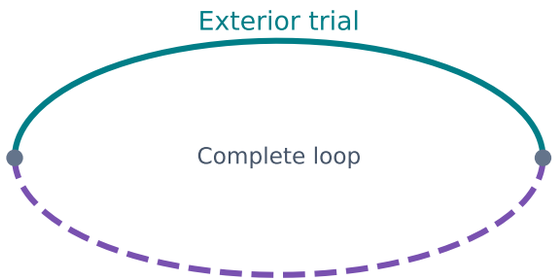
Charge response depends on the whole loop

Neutral equilibrium for each independent channel • Leading rotation order • Prescribed optical lengths

A. The complete optical average enters the response



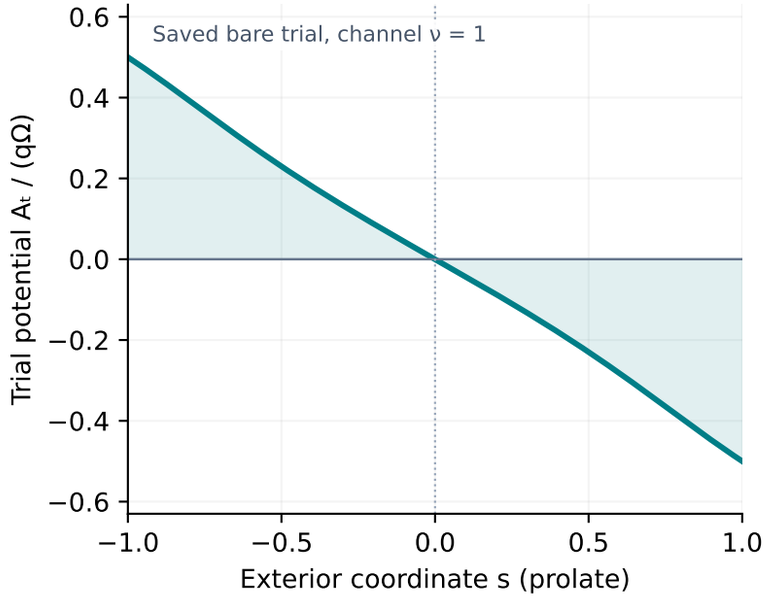
Throat: mean potential unknown

$$j_{\text{neutral}} = (A_t - \langle A_t \rangle_{\text{loop}})/\pi$$

Subtract the whole-loop optical mean.

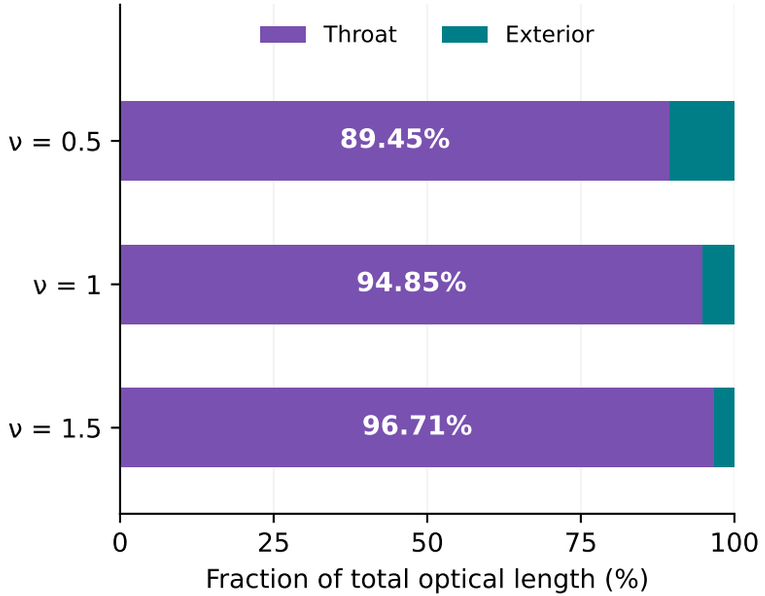
j is channel charge density in optical coordinates.
Throat attachment and state unresolved; diagram not to scale.

B. An odd exterior trial cancels by reflection



Odd potential × even optical weight: exterior integral = 0.
Exterior parity alone does not fix the throat mean.

C. Most prescribed optical length lies in the throat



Fractions of prescribed optical length, not research completion or solved field strengths. The throat mean is unknown.

Bosonized action: MMP, Appendix G. Closed neutral-loop projection and parity checks: our constrained application.

The cancellation uses a symmetric zeroth-order optical measure and an odd first-order potential; no full rotating state is established.

No stable medium or 13 → 12 Sep 2027 passage established. **Forward branch unchanged.**
