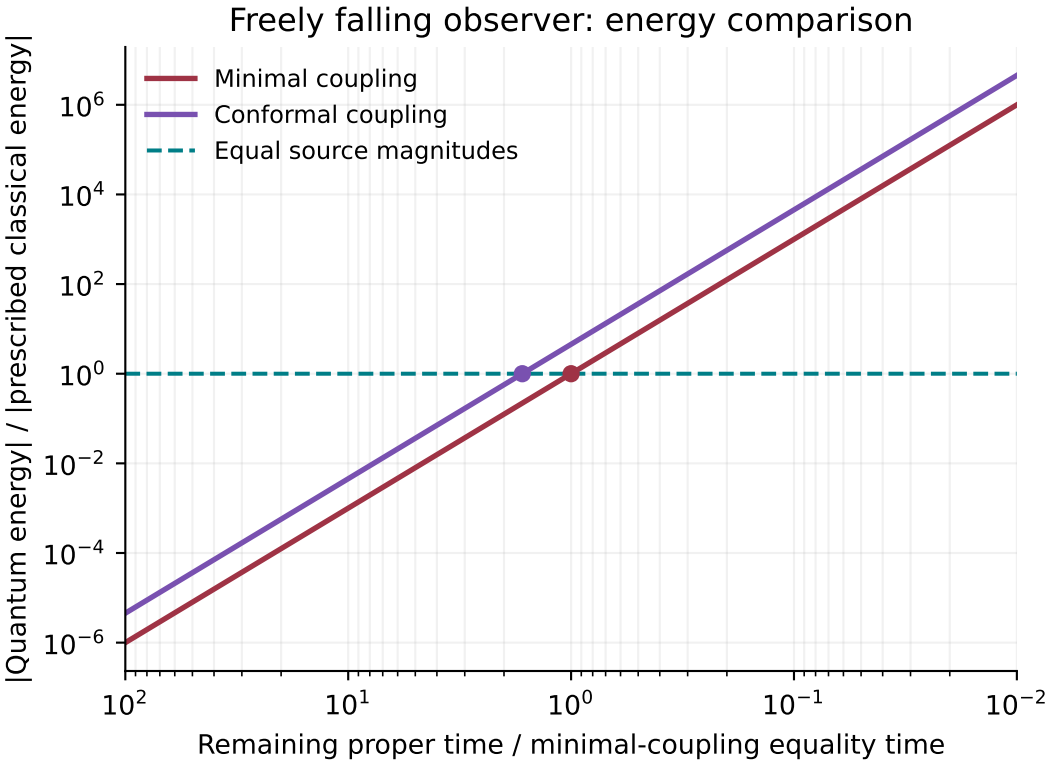
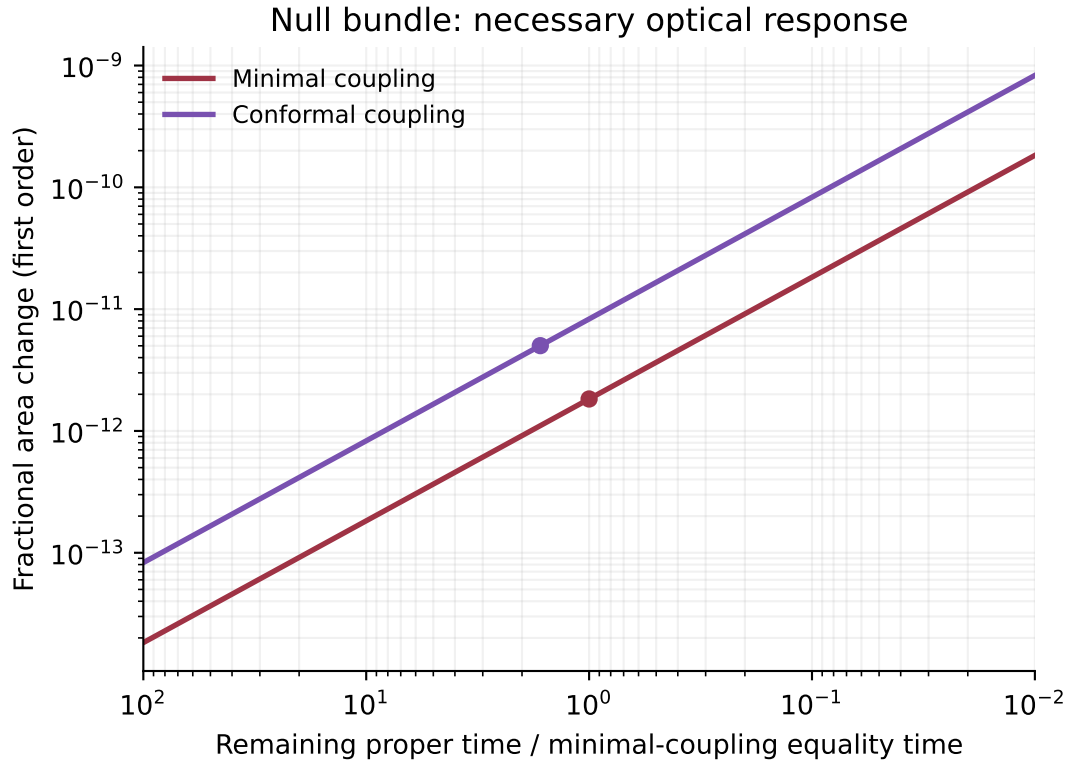
A tiny light-bundle change does not establish stability

Calculated quantum energy grows faster than this first-order area response

Model: $\eta = 10^{-12}$, observer $q = 1/\sqrt{2}$; initial beam area = 1 and expansion = 0 at $T = -1$





Dots mark equal quantum and classical energy magnitudes. The first-order area change there is only about 10^{-12}.

Both calculations start from the prescribed state and geometry. This is not a simulation of a stable medium.

Right: the z-invariant null congruence is sampled along the observer's path; the observer does not travel with one beam.

13 September 2027 → 12 September 2027: no demonstrated crossing or calendar mapping.
