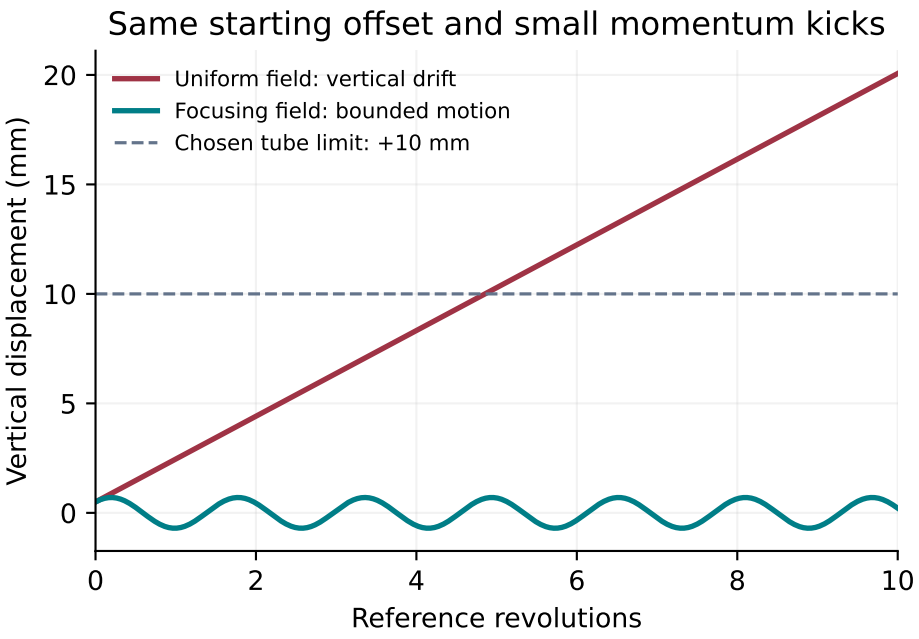
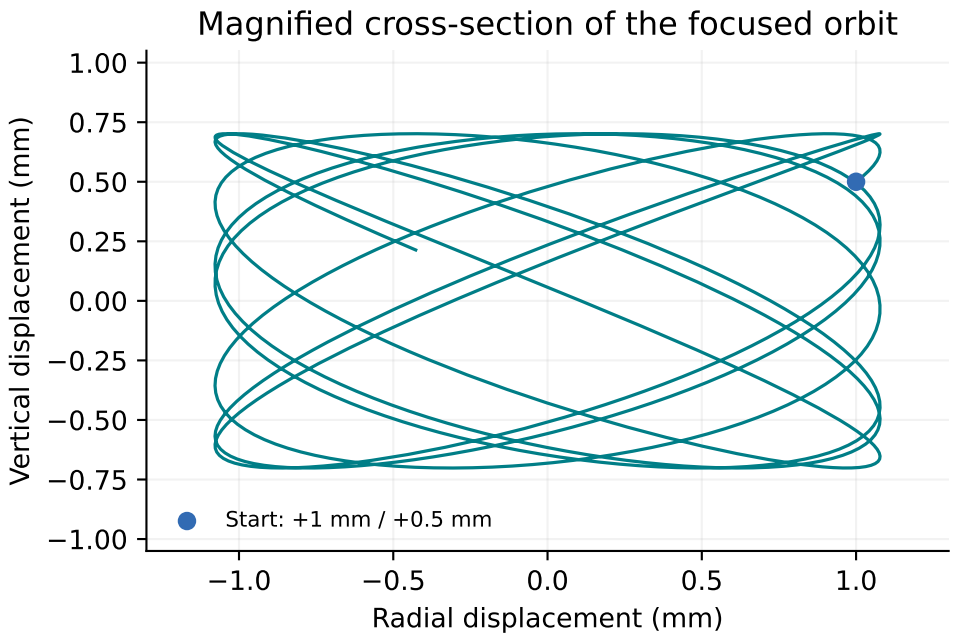
Future route: the focusing field contains a disturbed proton

Calculated ideal field: 1 T at a 31.14 m orbit radius • focusing index n = 0.4





100-turn check: focused motion stays within 1.08 mm radially and 0.71 mm vertically; uniform-field vertical drift reaches 196 mm.

An energy bound also prevents escape in the ideal static model. Radiation, RF, field errors and injection are outside this bound.

100 turns ≈ 65.6 microseconds. This is progress toward confinement, not a demonstrated one-day trip.
