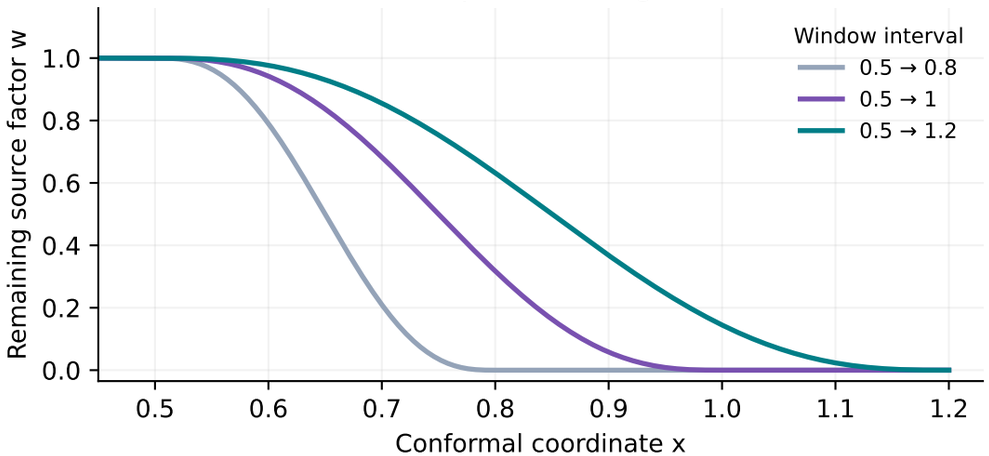
Source tapering requires pressure; receiver timing changes the outcome

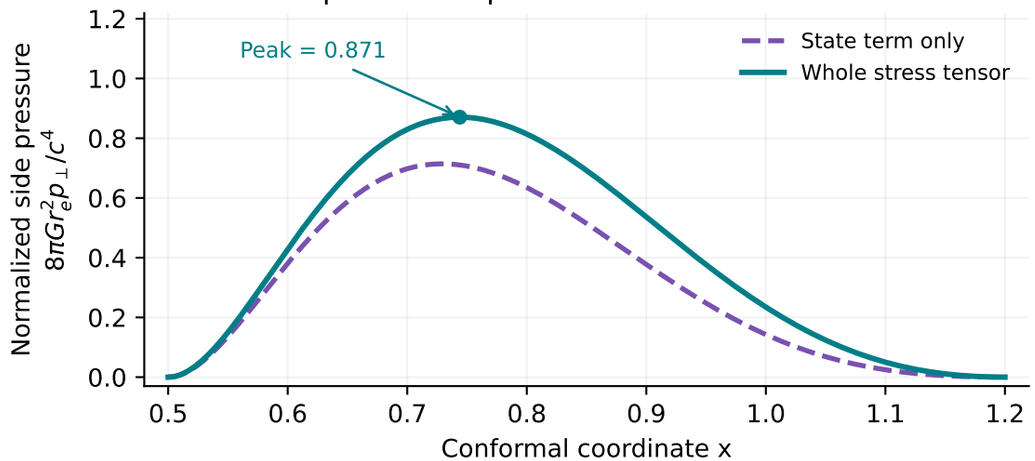
Separate theoretical tests • held-fixed throat geometry and prescribed receiver currents • no built time machine

A. Three imposed fading windows



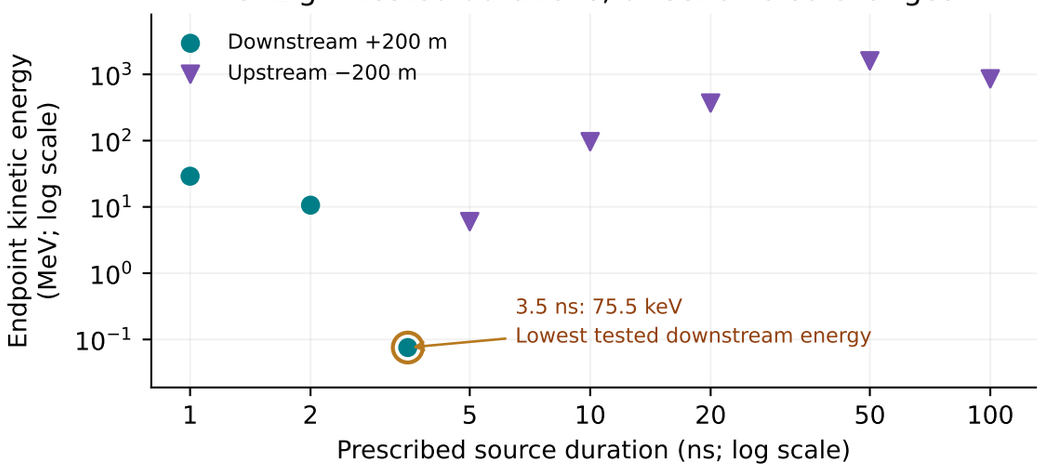
The background geometry is kept fixed
A consistent quantum source remains unproved

B. Required side pressure in the widest window

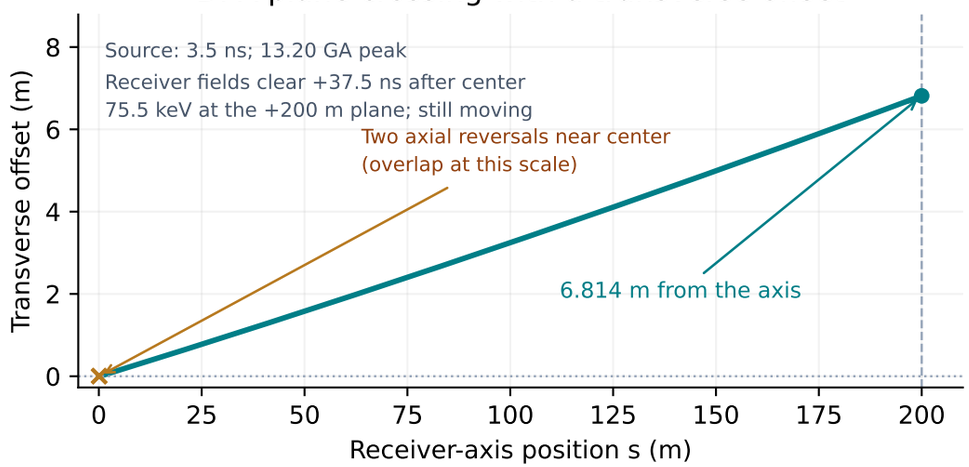


Any monotone whole-stress taper on x = 0.5–1.2 needs
max(side pressure / |original radial pressure|) ≥ 3.87 × 10⁸

C. Eight tested durations; direction also changes



D. A plane crossing with a transverse offset



Different axis scales; no point-target acceptance or capture test

Tapers: α = 1e-09; geometry held fixed. Pressure alone supplies no consistent quantum theory, gravitational response or stable join.

Receiver: a classical test proton with prescribed currents. Capture, target acceptance, practical current generation and reunion remain unproved.

13 → 12 Sep 2027: unproved. **Forward time dilation is supported; a complete one-day journey remains untested.**
