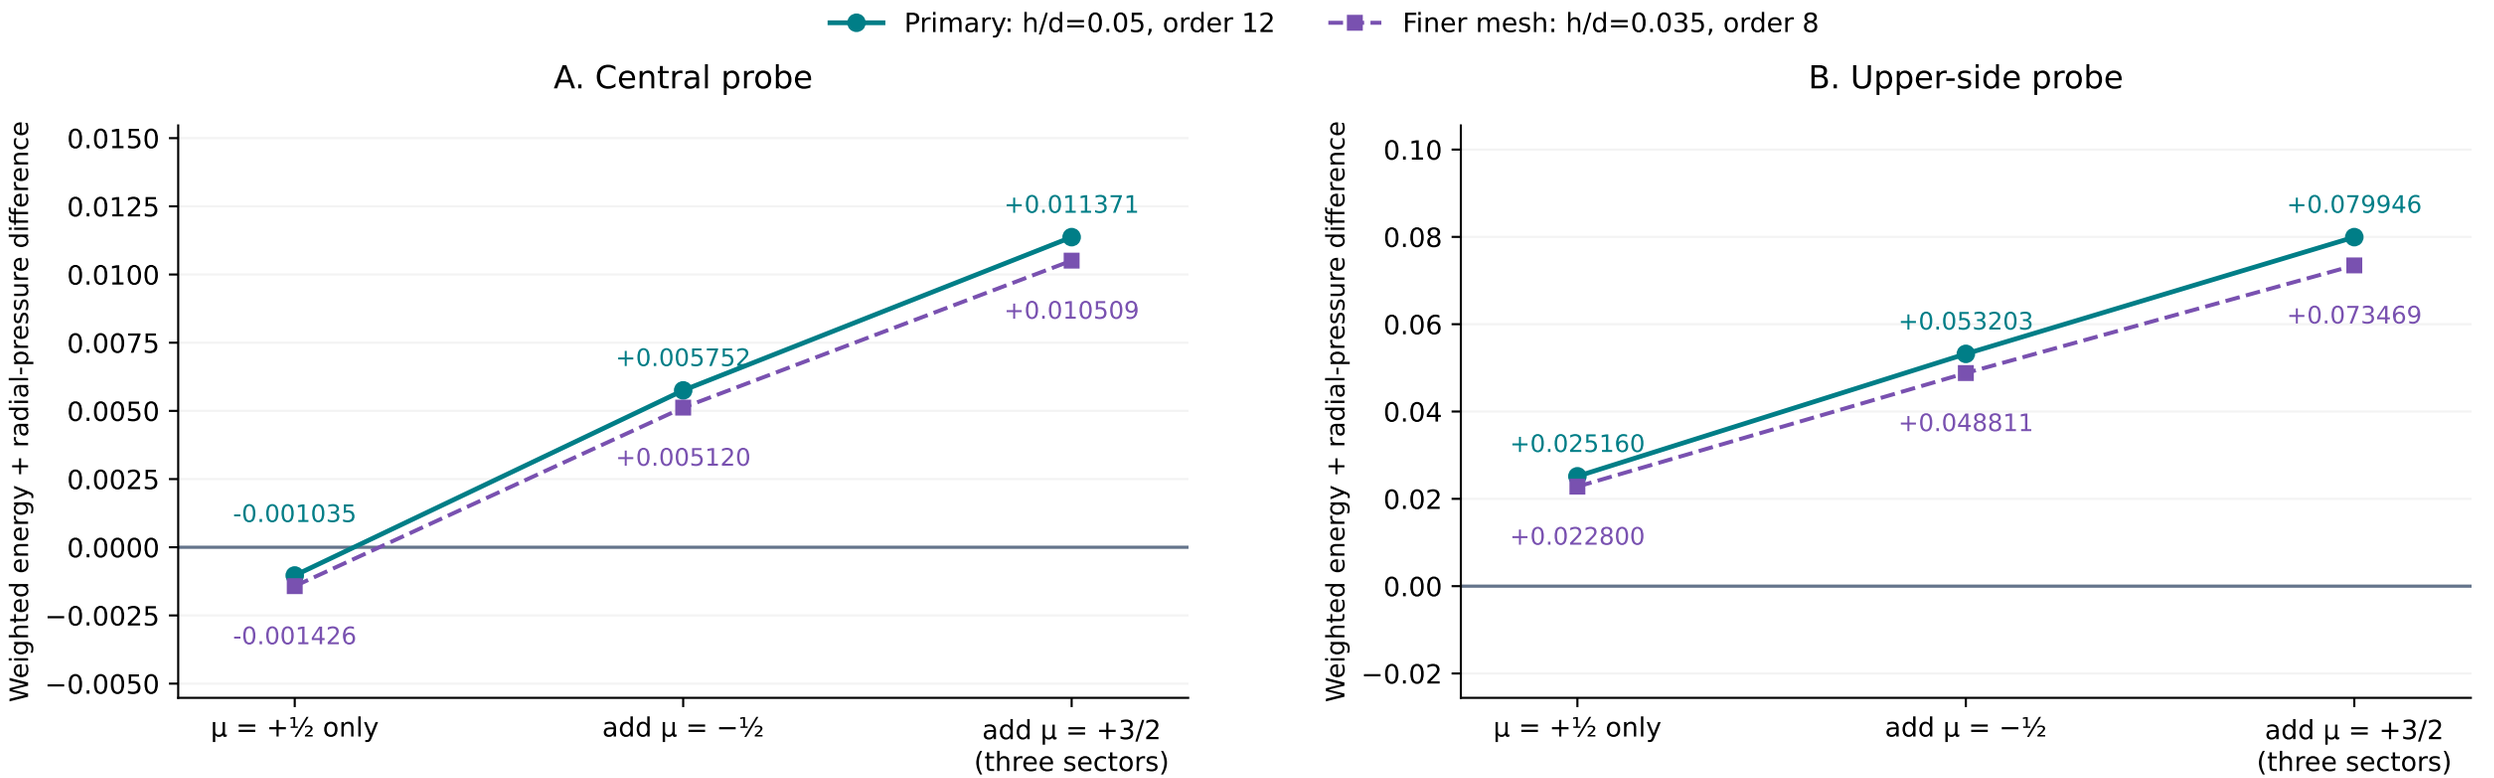
The central reference difference changes sign in the partial sum

Phase π · Connected minus invariant AdS reference · Same prescribed core and endpoint connection



Each point adds an explicitly computed sector; no angular degeneracy multiplier is used.

$\hbar$ = c = d = 1; finite window 1e-06 ≤ κd ≤ 96. Both Weyl components are retained.

Final sum: matched-order mesh changes 0.000862 (central), 0.00648 (upper); frequency-panel sensitivity 1.5e-09.

These are numerical sensitivities, not certified error bounds. Three sectors do not complete the angular source or its supporting geometry.

A reference-relative partial sum does not establish absolute NEC violation, a physical junction or stability.

No stable medium or 13 Sep 2027 → 12 Sep 2027 passage demonstrated.
