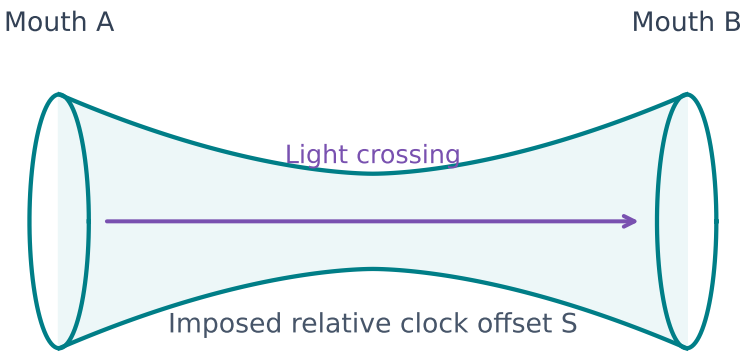
Tested static clock offsets still give later exits

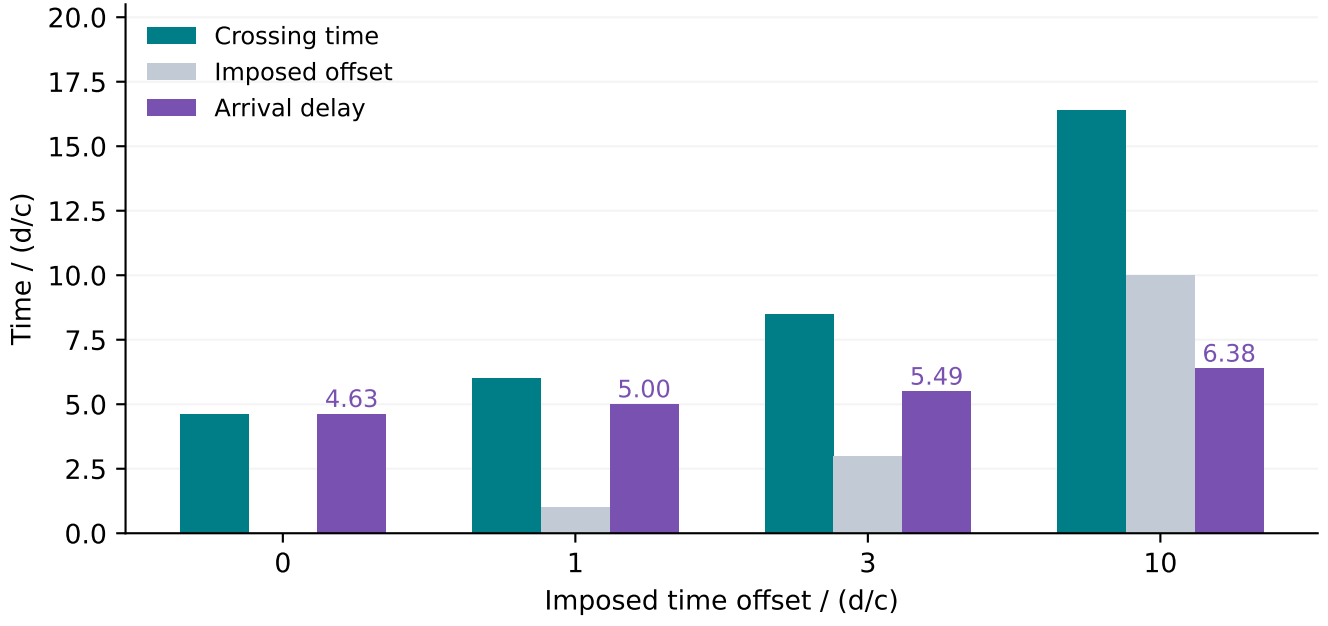
Separate assumed states, not a preparation sequence | Times in d/c units; no calendar conversion

A. Assumed geometry — schematic only



Arrival delay = crossing time − offset
Positive means arrival is still later.

B. Static offset: no past exit in the four tests



The static mean-throat crossing time increases as the imposed offset increases.

Small clock perturbations: no exponentially growing mode in either linear sector.

Zero-offset NS vacuum only • fixed delays • $b_0 > 0$. Neutral modes remain; this does not establish damping or nonlinear stability.

Moving exterior and physical preparation remain unresolved; the pictured geometry is assumed, not constructed.

No stable material or 13 → 12 Sep 2027 passage demonstrated.
