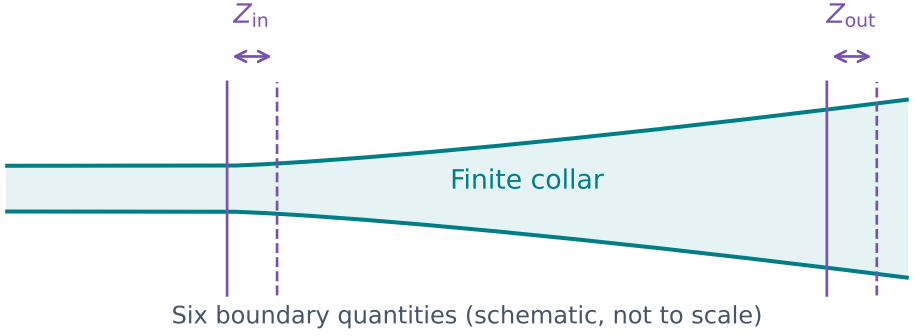
Boundary response derived; actual matching unresolved

Assumed static throat and channel model • One collar only • Common center-time normalization; $r_e = 1$

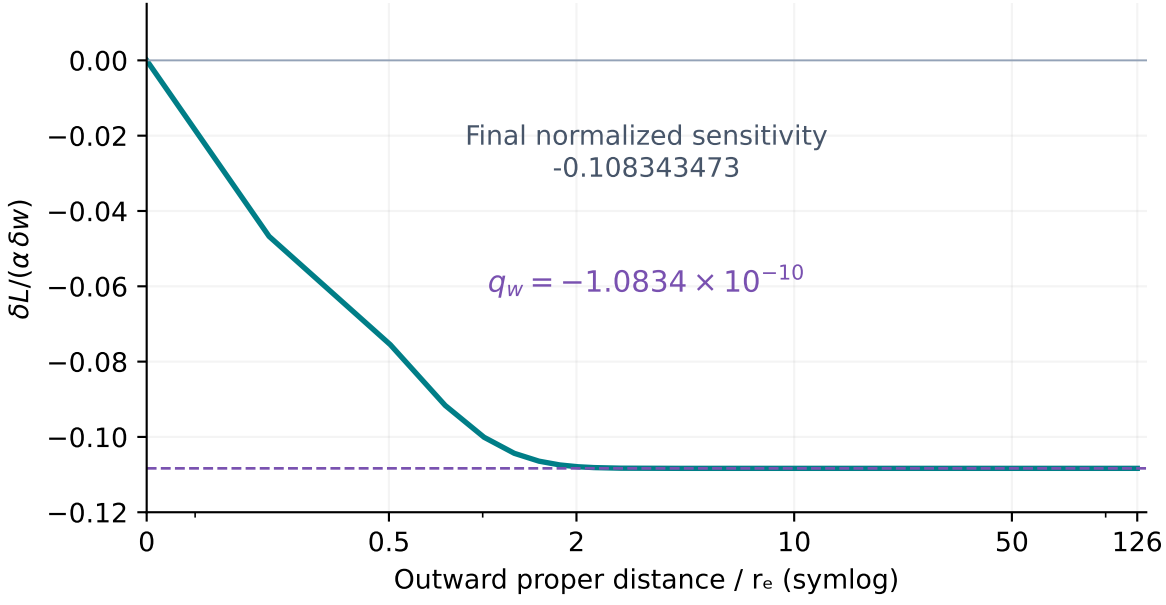
A. Geometry and fields at movable cuts



- Clock rate (lapse)
- Angular metric
- Time curvature
- Angular curvature
- Flux / area contrast
- Magnetic boundary response

Inner cut x = 0.5; outer cut radius = 100 r_e.
Z denotes invariant cut displacement; end values remain inputs.

B. Source sensitivity of this collar



P and cut displacements are held fixed as the source varies.
This is a static sensitivity, not a backward-time trajectory.

$$\delta L = q_{\text{in}} P_{\text{in}} + q_{\text{out}} P_{\text{out}} + q_w \delta w + Z_{\text{out}}/N_{\text{out}} - Z_{\text{in}}/N_{\text{in}}$$

Physical end conditions, outside path, other mouth, complete-loop state and stability remain unresolved.

No constructed stable medium or 13 → 12 Sep 2027 passage established.
