A computed exterior wave, with explicit model boundaries

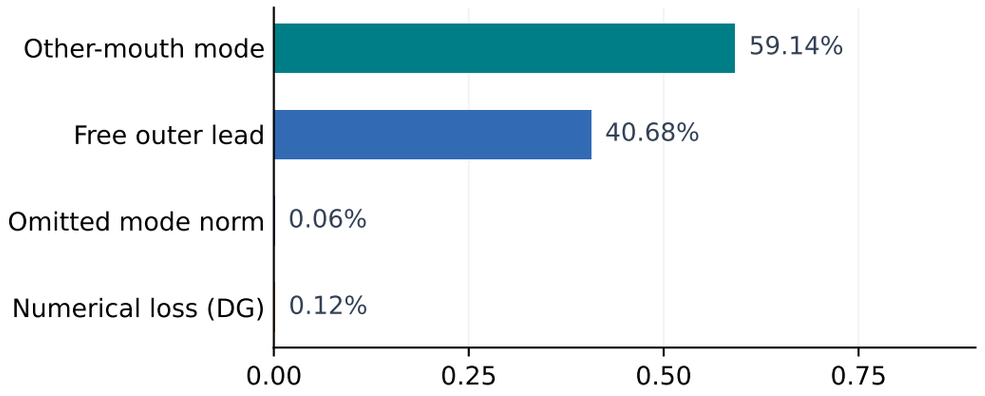

q = 1 | μ = 1/2 | E d = 0.4 | Unit incident current | No physical throat matching

A. Computed wave intensity

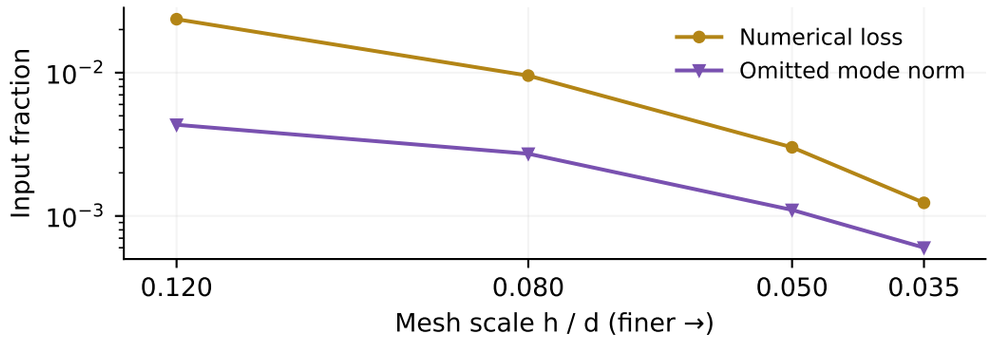

Near-mouth crop; whole-domain radius R = 4 d.

B. Fractions of unit model input

C. Mesh refinement at R = 2 d, mode cutoff = 8

Outer-radius dependence: R/d = 2 → 4 → 8 gives other-mouth model flux 64.87% → 58.99% → 59.48% (fixed h = 0.05 d).

Specified product mouth leads and free outer map. Field intensity is not a particle path; exterior convergence remains unresolved.

These conditional fluxes do not establish a physical return/escape probability or a stable medium.

13 Sep 2027 → 12 Sep 2027 remains unproved. This is a model calculation, not a new physical law.
