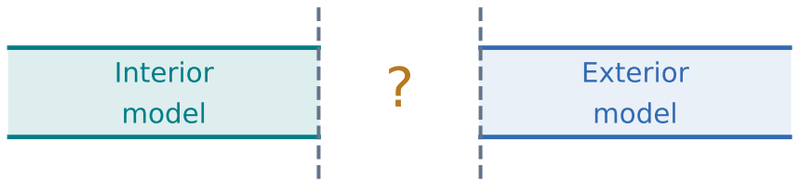
Exterior response tested; receiver discharge reflects the proton

Separate gravity and receiver tests • prescribed sources • no built medium or capture

A. A new exterior input; no joined medium yet

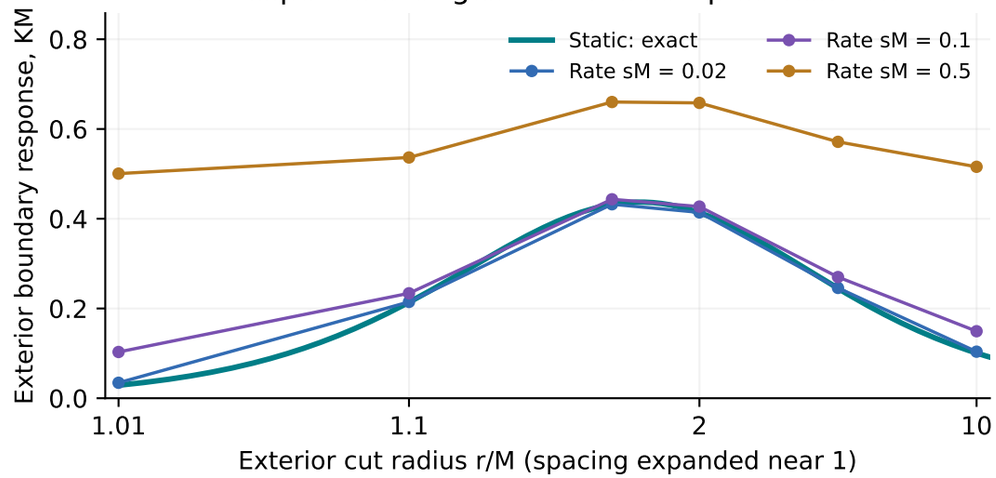
Field + metric response in each model



The physical mouth junction is not solved

Common fields, geometry, clocks and quantum response must be matched; this is a domain sketch

B. Response changes with the sampled test rate



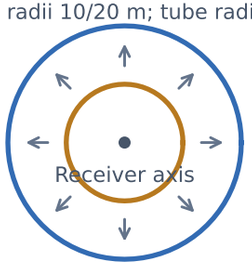
Positive real Laplace test rates sM

Not a complete causal boundary response

C. Discharge has an explicit current path

Initially +18.77 C inside and -18.77 C outside

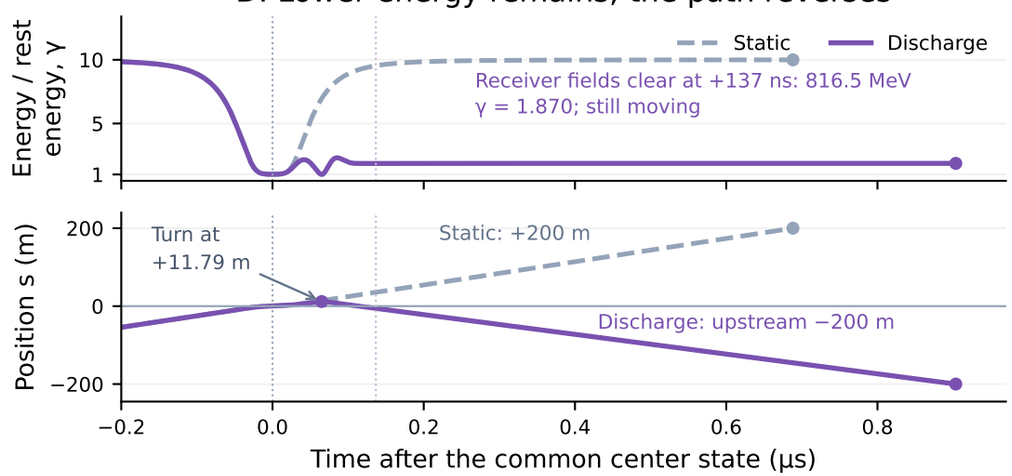
Top view: radii 10/20 m; tube radius 0.1 m



Source duration: 100 ns; peak current 461.9 MA

Edge current density diverges; no conductor design

D. Lower energy remains; the path reverses



Exterior: static positivity and sampled Laplace response. A physical mouth junction, quantum response and full stability remain open.

Initial receiver field: ≥ 6.355 GJ outside 20.2 m. This is a field-energy bound, not dissipation or driver demand.

13 → 12 Sep 2027: unproved. **Forward time dilation is supported; a complete one-day journey remains untested.**
