From an exterior field response to a conditional loop determinant

Imaginary energy is a calculation variable — these values are not probabilities or particle trajectories

Computed exterior

$T(i\kappa)$

Same numerical resolution below

Assumed throat connection

$z = e^{i\theta - \kappa\ell}$

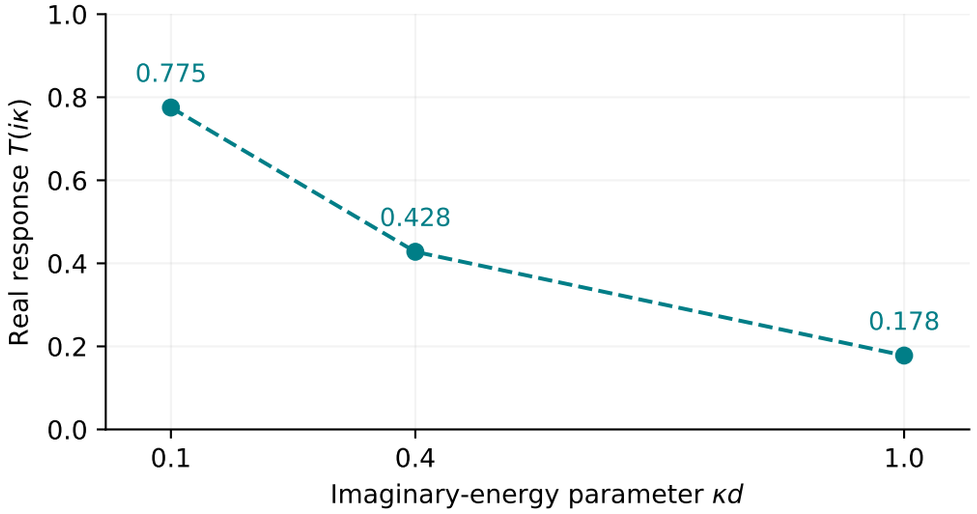
Length ℓ and phase θ are inputs

Conditional determinant

$D = 1 - zT$

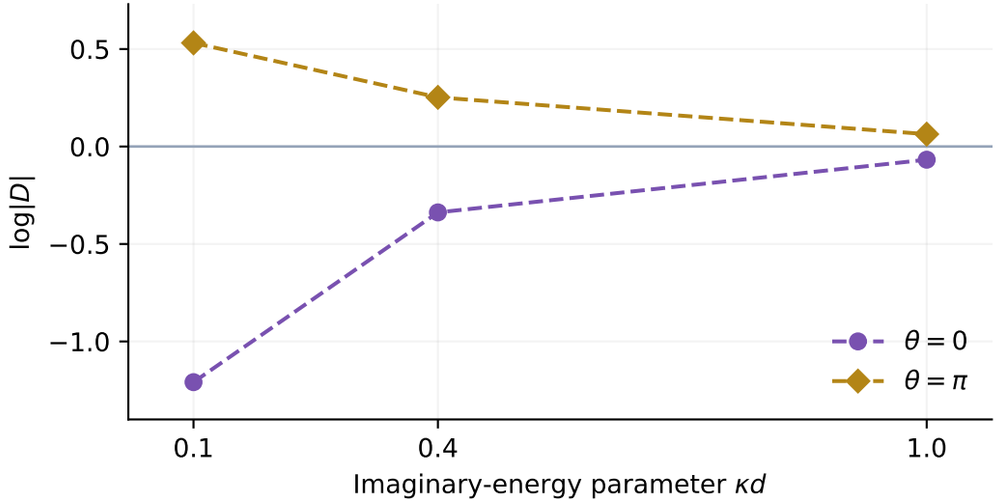
Finite boundary-matrix ratio

A. Sampled exterior response



Three computed samples; dashed segments guide the eye.

B. Same response, two assumed phases



Chosen optical throat length: ℓ / d = 1.

Both panels: q = 1, h/d = 0.08, R/d = 2, L/d = 40, mode cutoff 8; fixed product mouth leads.

The endpoint phase is not physically derived. A full vacuum stress tensor and a stable medium remain unproved.

No physical time-travel route or 13 Sep 2027 → 12 Sep 2027 passage demonstrated.
