An incoming field, orbital motion and an RF event test

Separate conditional models • No joined rotating throat or built transport system

A. Nearly fixed distance does not fix orientation

Local RN exterior
$1.01 \le r/r_e \le 4$

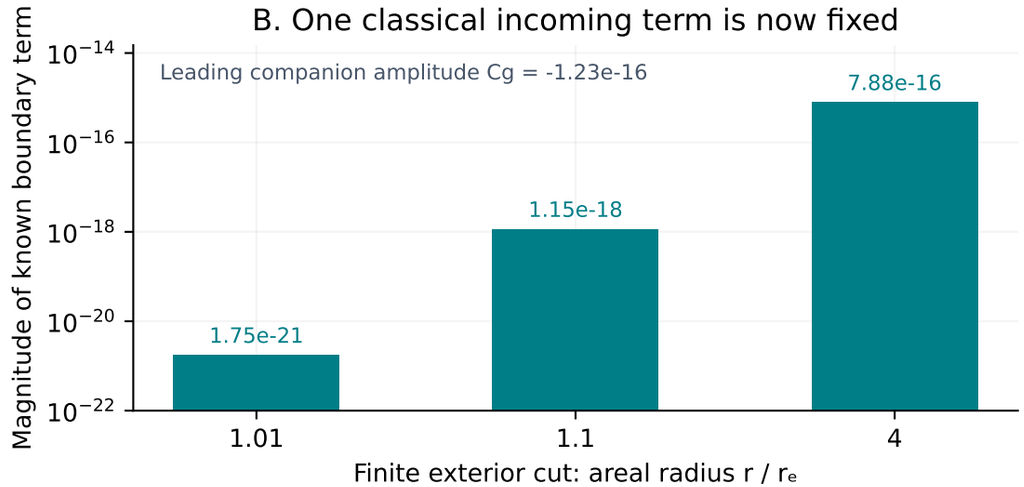

Orbital orientation change
0.4185°

Fractional distance decrease
2.71e-14

Schematic; angle shown 30×

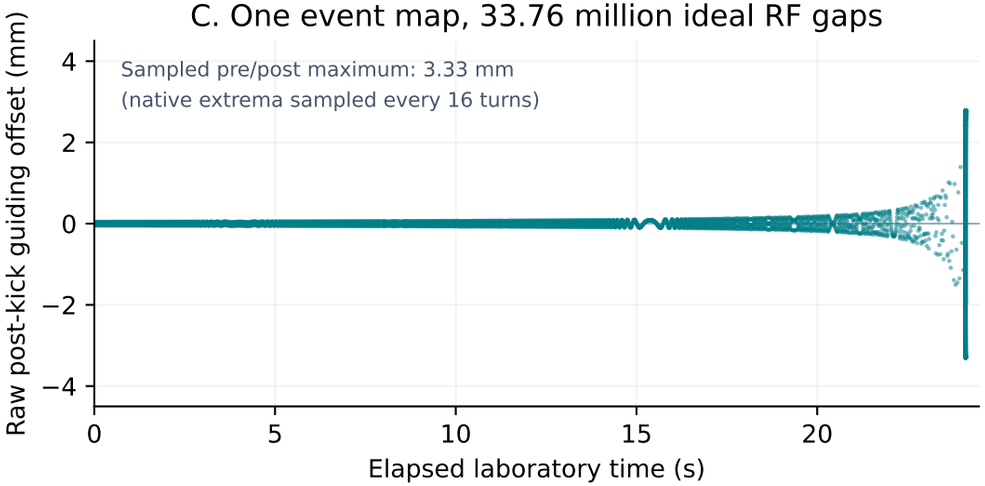

Assumed mouths with opposite magnetic charges; not to scale.
Values use the initial throat light-crossing scale $\pi\ell/c$, not a payload transit.

B. One classical incoming term is now fixed

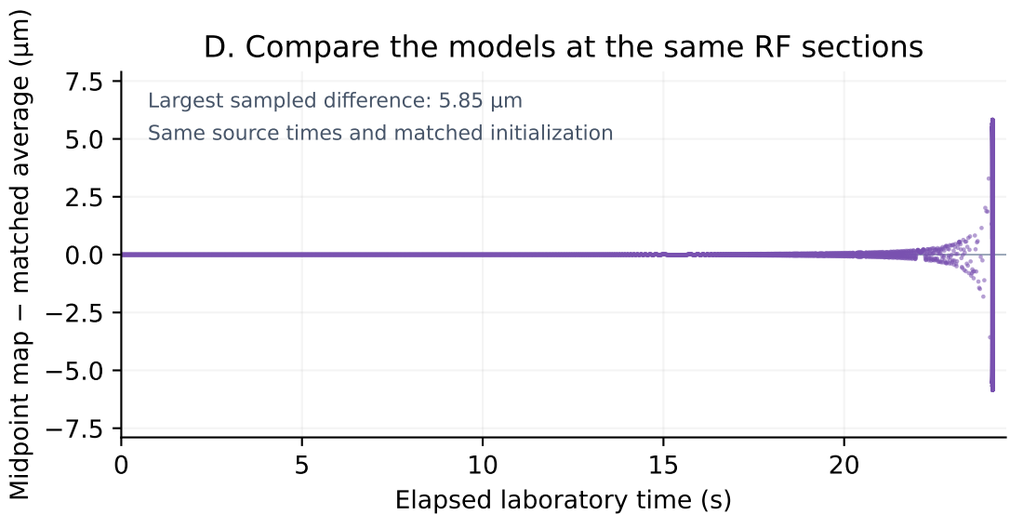

All three signed terms are negative. Quantum incoming data, the full source amplitude and physical throat matching remain unresolved.

C. One event map, 33.76 million ideal RF gaps

Points are saved post-kick samples, not a resolved whole-ramp trace.
Prescribed zero-length gaps; transverse motion is outside this model.

D. Compare the models at the same RF sections

Use the energy midpoint of each kick and a consistently initialized average.
This sampled comparison is not a continuous error bound.

Orbit: equal mouths share the leading clock rescaling; no relative offset is created. The rotating quantum state and throat matching remain open.

RF: one initial condition in a longitudinal reduction. Finite cavities, transverse coupling, a full beam distribution and permanent capture remain unproved.

13 → 12 Sep 2027: unproved. **Forward time dilation is supported; no complete human journey has been demonstrated.**
