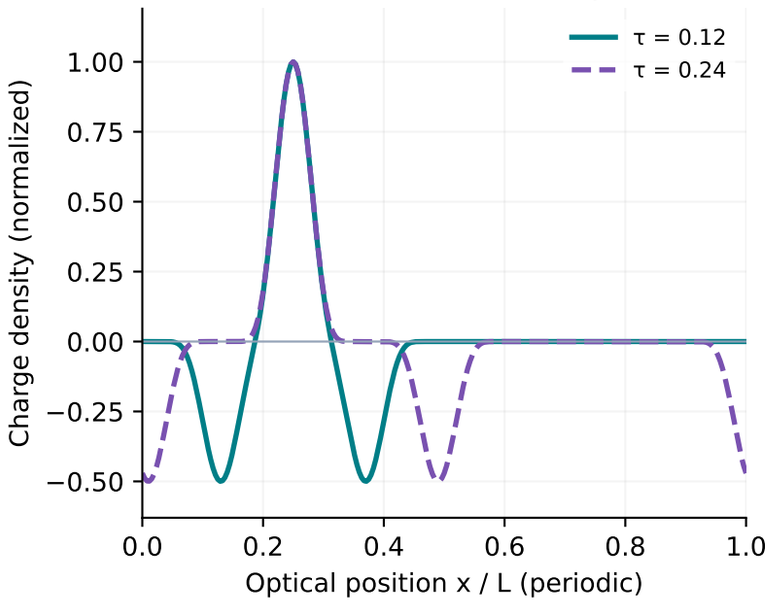
A timed drive cancels mean charge oscillations in one ideal loop

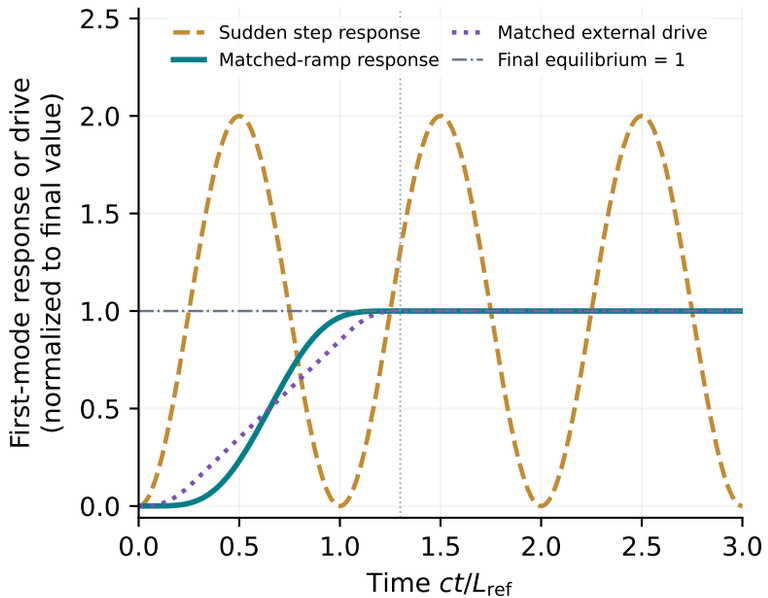
Prescribed static optical loop • External potential drive • No damping or physical source apparatus

A. Charge waves travel around the fixed loop



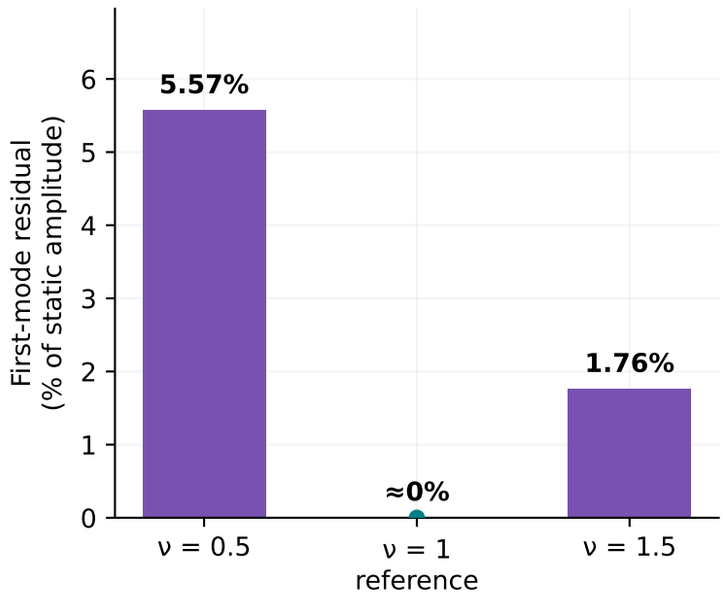
τ = ct/L; the plot ends are the same point on the loop.
Saved step-response profiles show causal propagation.

B. A specially timed ramp cancels the free transients



Ramp ends at $1.3L_{ref}/c$; first charge mode shown.
Cancellation is analytic for the free reference harmonics.

C. The same ramp does not cancel unequal loops



One common ramp on three prescribed loop lengths.
Residuals are relative to each static first mode.

Action: MMP, Appendix G. Retarded response and timed-ramp calculations: our application of that model.

A separate electromagnetic feedback test shifts the frequencies and leaves residual waves; actual coupled fields and throat matching remain unresolved.

No stable medium or 13 → 12 Sep 2027 passage established. **Forward branch unchanged.**
