Local magnetic polarization alone cannot open a regular static throat

Two separate diagnostics | One massless Dirac species | q = 100,000; g = 0.06283

A. Background change versus opening stress

Local magnetic vacuum polarization

$$\rho + p_r = 0$$

Changes the background; supplies no opening stress.

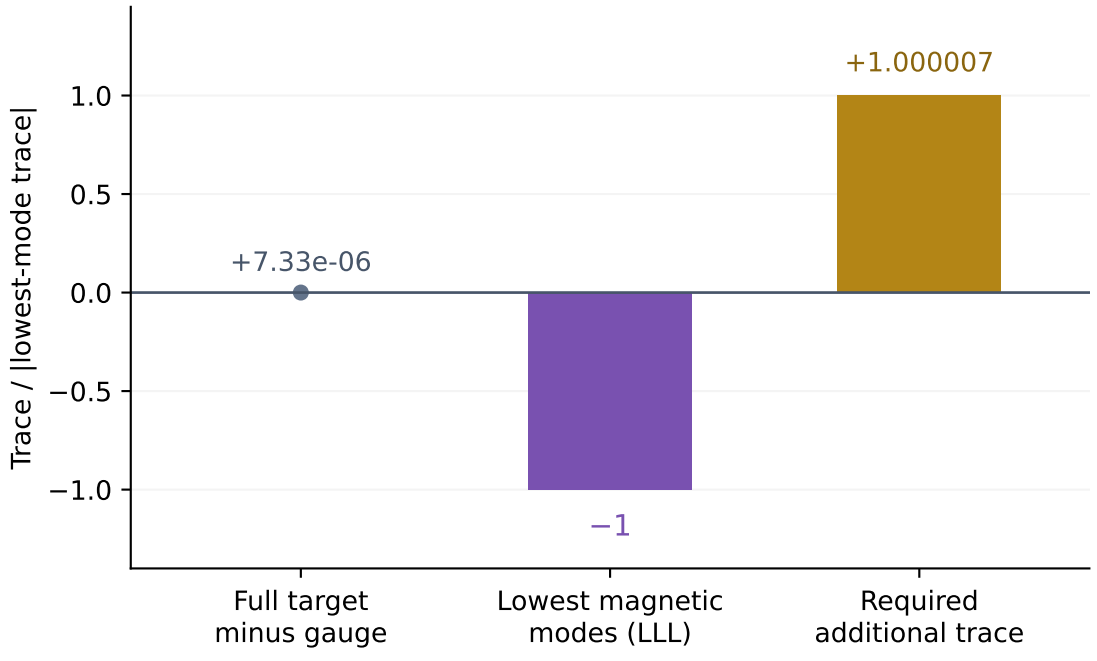
Loop Casimir contribution

Candidate $\rho + p_r < 0$

A complete four-dimensional source is still needed.

Local-model radius ratio: $L_a / R_s = 1.000016667$
This background shift does not demonstrate an open throat.

B. A missing trace of comparable size



Classical equal-radius RN throat, not the corrected metric.
Common gauge trace removed; vertical units are |LLL trace|.

The additional trace is a requirement, not an identified source; matching a trace does not determine a conserved stress tensor.

Renormalization, double counting, full four-dimensional matching and stability remain unresolved.

No constructed stable medium or 13 → 12 Sep 2027 passage demonstrated.
