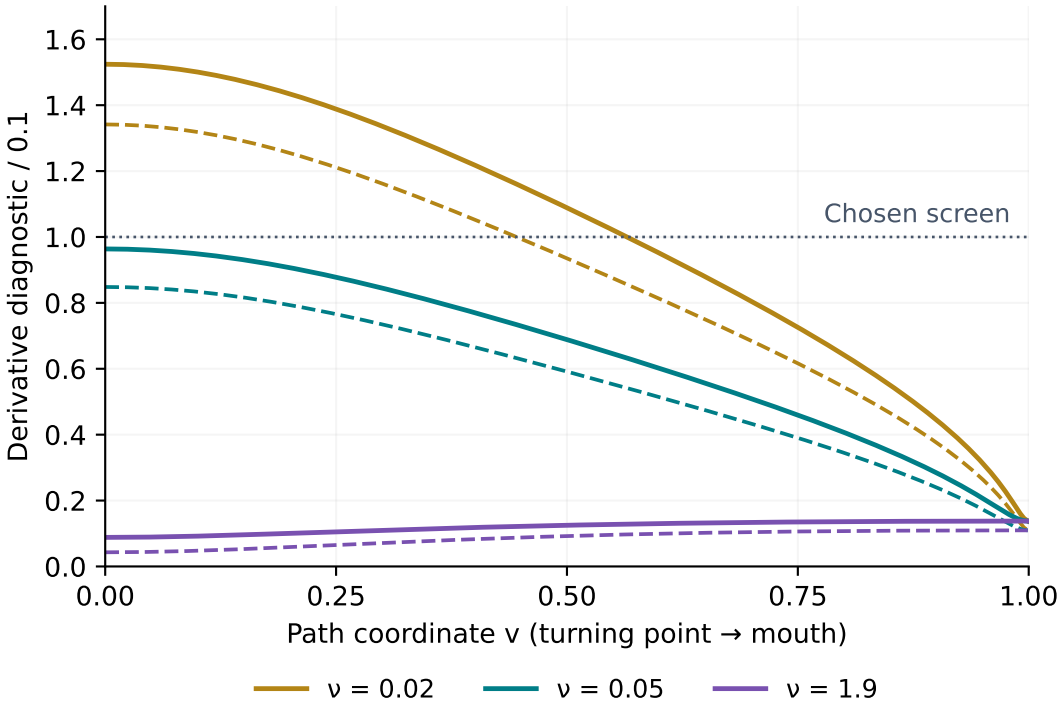
At least 2.32% of the modeled flux fails the chosen derivative screen

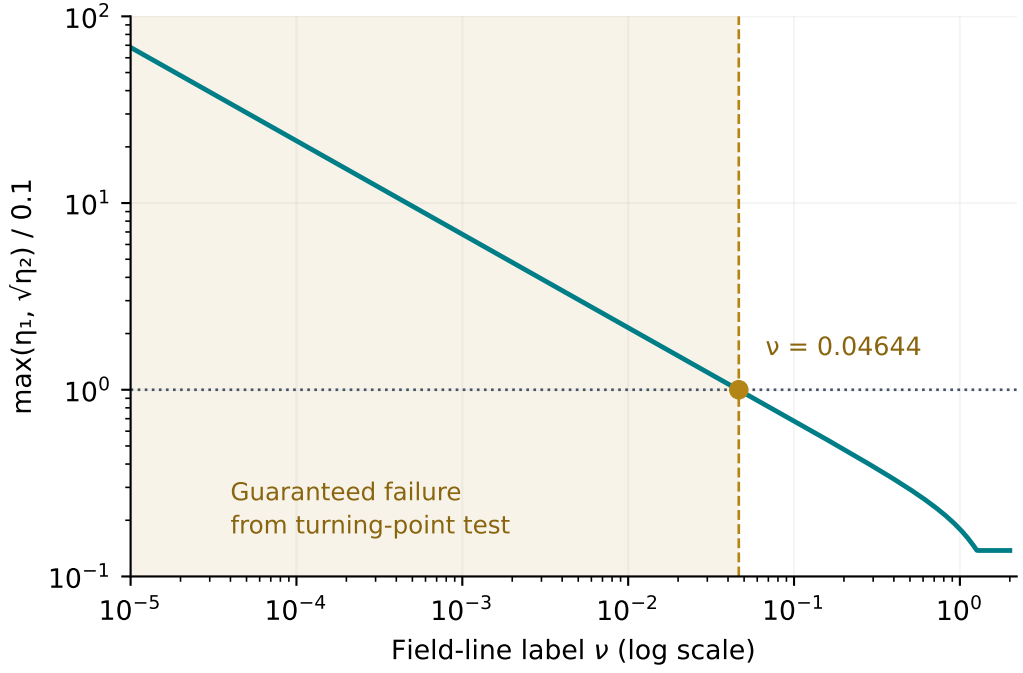
First and second Cartesian derivatives | Flat opposite point charges | q = 100,000

A. Diagnostics along three field lines



Solid: $\sqrt{\eta_2}/0.1$; dashed: $\eta_1/0.1$.

B. Largest diagnostic on each full path



At least 2.32% of continuous flux measure dν/2.

This is a flagged flux fraction, not an error fraction.

An exact counterexample at ν = 1.26 has η₂ larger inside the path than at either endpoint.

Higher-ν whole-path maxima are numerical scans. These chosen screens prove neither physical accuracy nor stability.

No constructed stable medium or 13 Sep 2027 → 12 Sep 2027 passage demonstrated.
