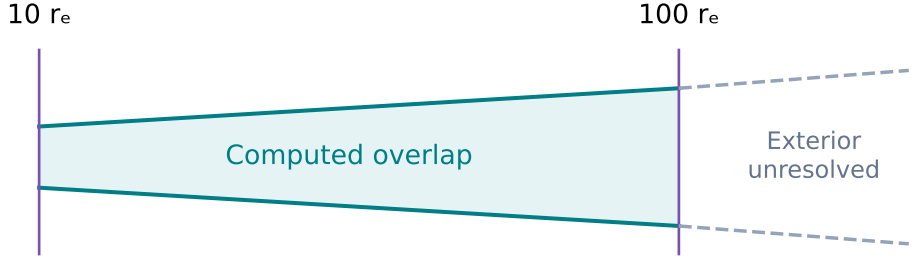
Local terms partly cancel; finite boundary correction remains

Static linear collar model • Computed region: radii 10–100 r_e • $\alpha = 10^{-9}$

A. Leading terms cancel after projection

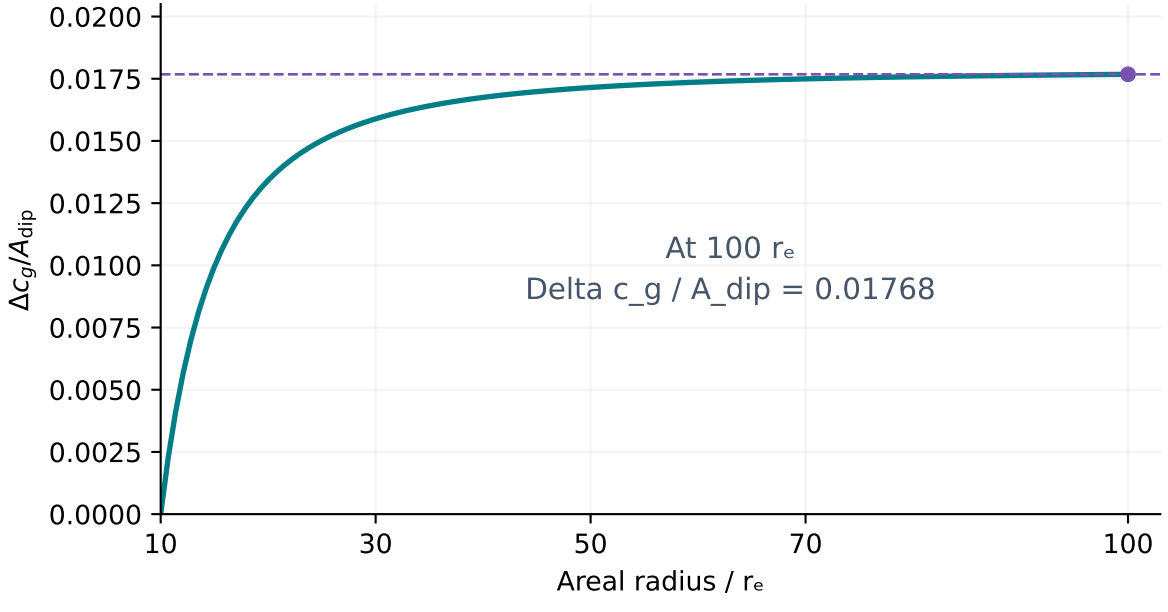


$$-\frac{4}{27r^2} + \frac{4}{27r^2} = 0$$

Next term: $-31/(27r^3)$

Schematic; first-order large-radius coefficients per k c_g, k = α/3.
These expansion terms do not determine the far exterior.

B. Cumulative correction for one test input



Curve: incident-induced correction only, normalized by A_dip.
Source forcing and an unknown decaying input are separate terms.

Declared growing-only input: $c_g = -2/d^2$. RN functions serve as a basis for the retained collar equations.

Physical endpoint data, the exterior return region beyond 100 r_e, complete-loop state and stability remain unresolved.

No constructed stable medium or 13 → 12 Sep 2027 passage demonstrated.
