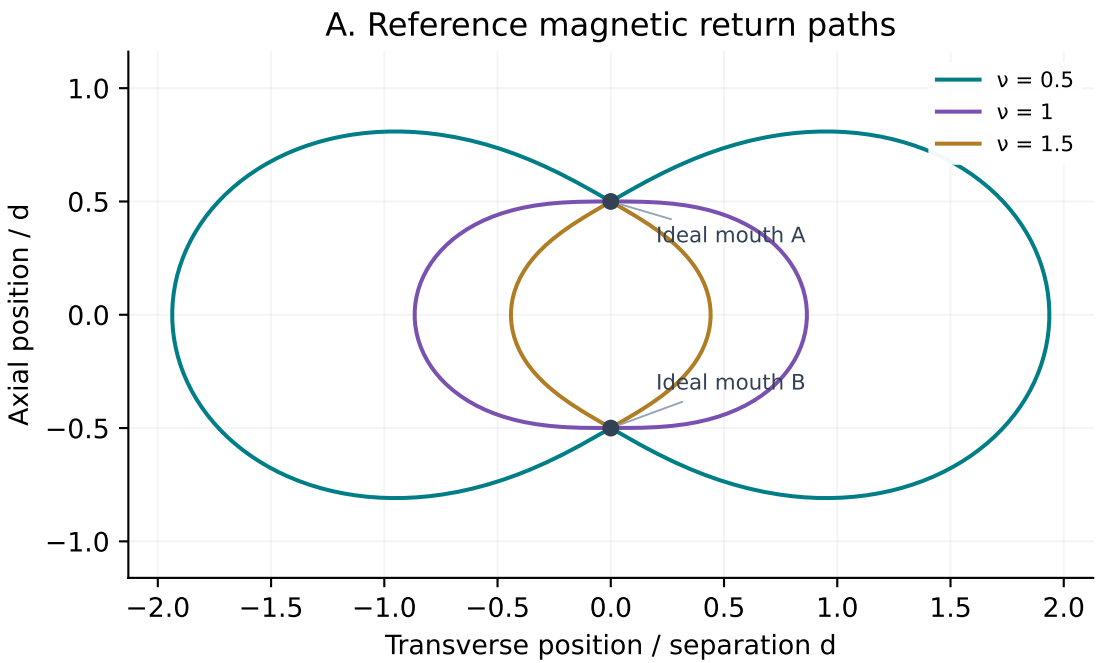
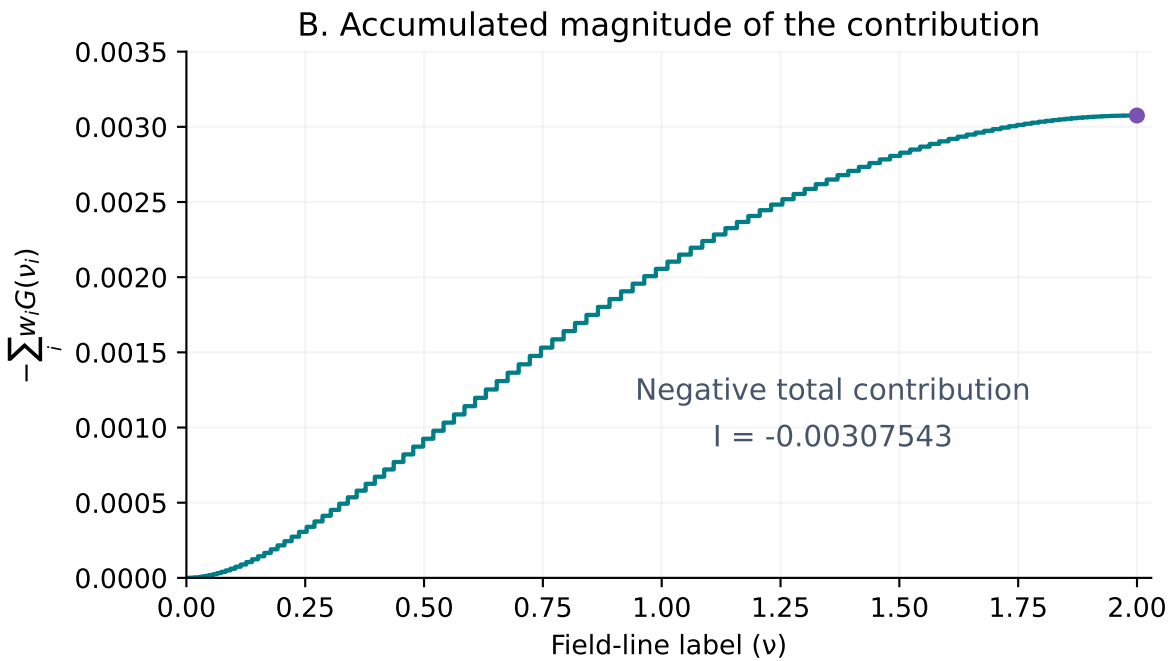
Returning channels give a negative magnetic contribution

Prescribed two-mouth magnetic geometry • Ideal flat-region model • Full saved channel weights • $\alpha = 10^{-9}$



Meridional slice of the theoretical field; mouth centers are idealized.
Smaller ν gives larger loops; ν → 2 approaches the direct path.



Discrete accumulated Gauss weights; not a continuous partial integral.
The positive curve displays the magnitude of a negative contribution.

$\delta c_{g,\,\mathrm{magnetic}} = 16\pi^2 \alpha I/d^2$: a source-generated field contribution, not a complete coupled boundary solution.

Finite-channel endpoint physics, curved-region/interface fields, the full metric and dynamical stability remain unresolved.

No material recipe, constructed stable medium or 13 → 12 Sep 2027 passage demonstrated.
