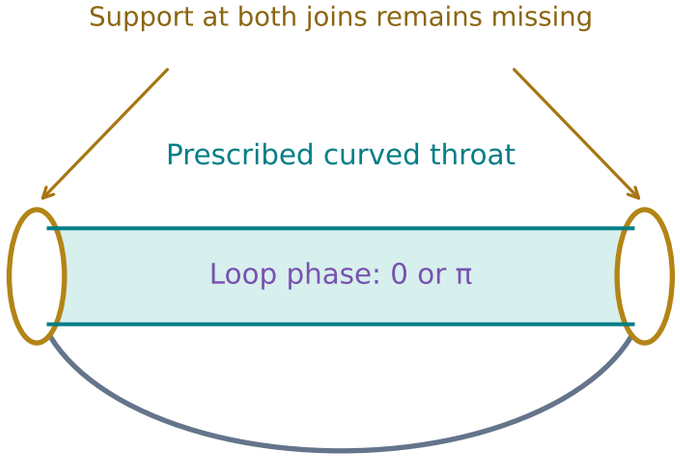
A finite phase contrast from the computed return field

One retained sector | Identical local geometry | Chosen loop phases 0 and π

A. Assumed loop geometry

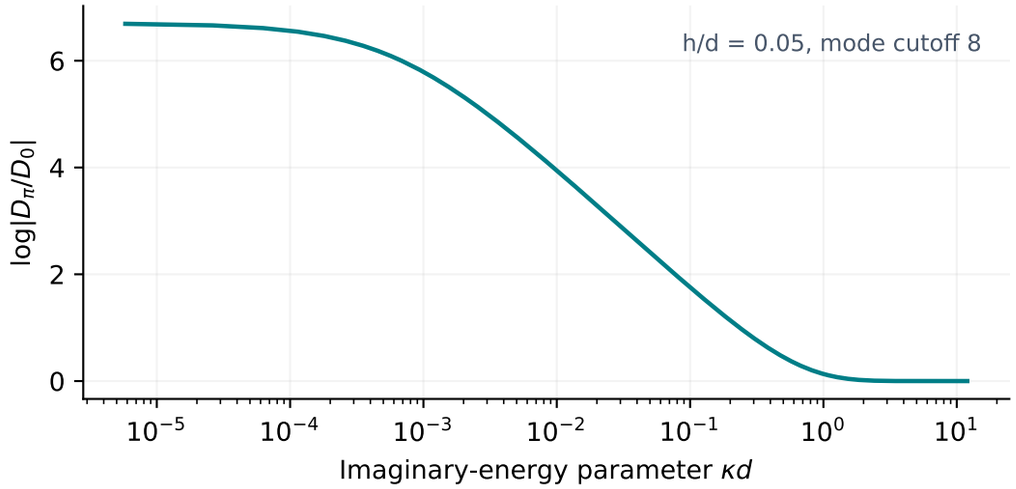


$$\Delta\mathcal{E} = -\pi^{-1}\int \log|D_\pi/D_0|\, d\kappa$$

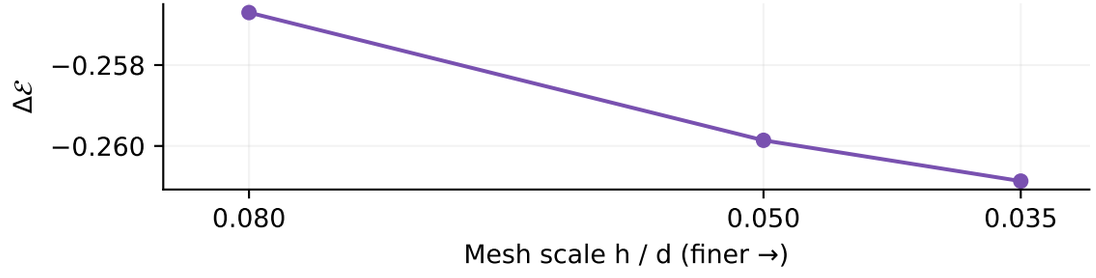
Finite-window contrast: -0.259860

Normalized model units ($\hbar$ = c = d = 1).

B. Saved integrand samples



Same finite window: mesh sensitivity



Finite window: 1e-06 ≤ κd ≤ 12. Latest mesh change: 0.00101; quadrature change: 3.2e-10.

Mesh changes are diagnostics, not certified errors. The low-frequency plateau may reflect numerical damping.

Uncomputed tails, full vacuum stress and the source supporting this synthetic geometry remain unresolved.

No stable medium or 13 Sep 2027 → 12 Sep 2027 passage demonstrated.
